

Aethera Sync Systems - Enterprise API Topography & Query Rout

3.1 Microservice Framework & Gateway Configuration

The core orchestration engine at Aethera Sync Systems exposes computational and retrieval logic via stateless asynchronous endpoints. The standard pathway for text query execution uses an active POST request structure pointed towards the URL location path `/ask``.

Payload structural contracts expect JSON body formats mapping a strict 'question' string literal. Response schemas return a structured JSON output holding 'answer' strings and an indexed array of 'sources' dictionaries indicating source files and exact page integers.

All internal communication nodes route traffic through an API Gateway layer using mutual TLS (mTLS) configurations. Services must authenticate using contextual authorization parameters embedded within standard protocol fields.

3.2 Rate Limiting and Concurrency Management

Rate limiting parameters restrict standard client tokens to an execution threshold of 100 API transactions per minute to protect localized operational workloads from memory spikes or service degradation.

Burst traffic up to 150 requests per minute is permitted for small windows under 15 seconds. If thresholds are broken, the gateway issues an HTTP 429 Too Many Requests response with a mandatory 'Retry-After' timestamp payload header.
